# Class6

## Winnie (A16673200)

Functions are how we get work done in R. We call functions to do everything from reading data to doing analysis and outputing plots and results.

All functions ifn R have at least 3 things.

- a **name** (you get to pick this)
- input **arguments** (there can be only one or loads again your call)
- the **body** (where the work gets done, this code between the curly brackets)

## A first silly function

Let's write a function to add some numbers. We can call it add()

```
x <- 10
y <- 10
x + y

[1] 20

add <- function(x) {
   y <- 10
   x + y
}</pre>
```

Can I just use my new function?

```
add(1)
```

[1] 11

Let's make it a bit more flexible.

```
add <- function(x, y=1) {
    x + y
}
add(x=10, y=10)

[1] 20
add(10)

[1] 11
add(10, 100)</pre>
```

## 2nd example grade() function

Write a function to grade student work.

We will start with a simple version of the problem and the following example student vectors:

```
# Example input vectors to start with
student1 <- c(100, 100, 100, 100, 100, 100, 90)
student2 <- c(100, NA, 90, 90, 90, 90, 97, 80)
student3 <- c(90, NA, NA, NA, NA, NA, NA, NA)

Start with student 1

mean(student1)

[1] 98.75

mean(student2, na.rm=TRUE)</pre>
```

```
mean(student3, na.rm=TRUE)
[1] 90
Ok lets try to work with student1 and find (and drop) the lowest score.
  student1
[1] 100 100 100 100 100 100 100 90
Google told me about min() and max().
  min(student1)
[1] 90
  which.min(student1)
[1] 8
  student1[8]
[1] 90
  student1[which.min(student1)]
[1] 90
  student1[-8]
[1] 100 100 100 100 100 100 100
```

Our first working snippet that drops the lowest score and gives us the mean.

```
mean(student1[-which.min(student1)])
[1] 100

x <- student1
mean(x[-which.min(x)], na.rm=T)</pre>
```

[1] 100

Our appraoch to the NA problem (missing homeworks): We can replace all NA values with zero.

1st task is find the NA values (i.e. where are they in the vector)

```
x <- student2
```

[1] 100 NA 90 90 90 97 80

```
x==90
```

[1] FALSE NA TRUE TRUE TRUE TRUE FALSE FALSE

```
is.na(x)
```

[1] FALSE TRUE FALSE FALSE FALSE FALSE FALSE

I have found the NA(TRUE) values from is.na() now I want to make them equal to zero (overwrite them/mask them etc.)

```
y <- 1:5
y
```

[1] 1 2 3 4 5

```
y[y>3] <- 0
y
```

#### [1] 1 2 3 0 0

I want to combine the is.na(x) with making these elements equal to zero. And then take this "masked" (vector of student score with NA values as zero) and drop the lowest and get the mean.

```
x <- student3
x[is.na(x)] <- 0
mean(x[-which.min(x)])</pre>
[1] 12.85714
```

Now I can turn my most awesome snipet into my first function.

```
grade <- function(x) {
    # Make NA (missing work) equal to zero
    x[is.na(x)] <- 0
    # Drop lowest score and get mean
    mean(x[-which.min(x)])
}
grade(student1)</pre>
```

#### [1] 100

Q1. Write a function grade() to determine an overall grade from a vector of student homework assignment scores dropping the lowest single score. If a student misses a homework (i.e. has an NA value) this can be used as a score to be potentially dropped. Your final function should be adquately explained with code comments and be able to work on an example class gradebook such as this one in CSV format: "https://tinyurl.com/gradeinput" [3pts]

```
url <- "https://tinyurl.com/gradeinput"
gradebook <- read.csv(url, row.names = 1)
head(gradebook)</pre>
```

```
hw1 hw2 hw3 hw4 hw5
                73 100
student-1 100
                        88
                             79
student-2
           85
                64
                    78
                        89
                             78
                    77 100
                             77
student-3
           83
                69
student-4
           88
               NA
                    73 100
                             76
                    75
                        86
student-5
           88 100
                             79
student-6
           89
                78 100
                        89
                             77
```

The apply() function in R is super useful but can be a little confusing to begin with. Lets have a look how it works.

```
ans <- apply(gradebook, 1, grade)
ans</pre>
```

```
student-1
            student-2
                       student-3
                                   student-4
                                              student-5
                                                          student-6
                                                                      student-7
     91.75
                82.50
                            84.25
                                       84.25
                                                   88.25
                                                              89.00
                                                                          94.00
student-8
            student-9 student-10 student-11 student-12 student-13 student-14
     93.75
                87.75
                            79.00
                                       86.00
                                                   91.75
                                                              92.25
                                                                          87.75
student-15 student-16 student-17 student-18 student-19 student-20
     78.75
                89.50
                            88.00
                                       94.50
                                                   82.75
                                                              82.75
```

Q2. Using your grade() function and the supplied gradebook, Who is the top scoring student overall in the gradebook? [3pts]

```
which.max(ans)
student-18
18
max(ans)
```

#### [1] 94.5

Q3. From your analysis of the gradebook, which homework was toughest on students (i.e. obtained the lowest scores overall? [2pts]

```
homework <- apply(gradebook, 2, mean, na.rm=TRUE)
homework</pre>
```

hw1 hw2 hw3 hw4 hw5 89.00000 80.88889 80.80000 89.63158 83.42105

```
which.min(homework)
hw3
  3
  min(homework)
[1] 80.8
     Q4. Optional Extension: From your analysis of the gradebook, which homework
     was most predictive of overall score (i.e. highest correlation with average grade
     score)? [1pt]
  #ans
  cor(gradebook$hw1, ans)
[1] 0.4250204
  #ans
  cor(gradebook$hw5, ans)
[1] NA
  gradebook$hw5
          78 77 76 79 77 100 100 77 76 100 100 80 76 NA 77 78 100 79
 [1]
[20]
      76
  mask <- gradebook
  mask[is.na(mask)]<-0</pre>
  mask
```

```
hw1 hw2 hw3 hw4 hw5
                          88
student-1
            100
                 73 100
                              79
student-2
             85
                 64
                     78
                          89
                              78
                 69
                     77 100
                              77
student-3
             83
                     73 100
student-4
             88
                  0
                              76
                          86
student-5
             88 100
                     75
                              79
student-6
             89
                 78 100
                          89
                              77
student-7
             89 100
                     74
                          87 100
student-8
             89 100
                     76
                          86 100
student-9
             86 100
                     77
                          88
                              77
                 72
                      79
                              76
student-10
            89
                           0
                     78
                          84 100
student-11
             82
                 66
                 70
student-12 100
                      75
                          92 100
             89 100
                      76 100
student-13
                              80
                     77
student-14
             85 100
                          89
                              76
student-15
             85
                 65
                      76
                          89
                               0
student-16
             92 100
                     74
                          89
                              77
student-17
             88
                 63 100
                          86
                              78
student-18
                  0 100
                          87 100
             91
student-19
                 68
                     75
                          86
                              79
             91
student-20
            91
                 68
                     76
                          88
                              76
```

```
cor(mask$hw5, ans)
```

### [1] 0.6325982

Now we can use apply() to examine the assignment in the masked gradebook to the overall score for each student in the class

```
apply(mask, 2, cor, y=ans)

hw1 hw2 hw3 hw4 hw5
0.4250204 0.1767780 0.3042561 0.3810884 0.6325982
```

Homework 5 has the highest correlation and most predictive of overall score.
